Directions:

CIS 5000 Final Exam

- Before beginning the exam, please write your random 4-digit number (not your name or PennKey!) at the bottom of each odd-numbered page, so that we can find things if a staple fails.
- You have 120 minutes to complete the exam.
- There are 110 total points (regardless of which track you follow).
- This exam contains both standard and advanced-track questions. Questions with no annotation are for *both* tracks. Other questions are marked "Standard Track Only" or "Advanced Track Only."
- *Do not waste time (or confuse the graders) by answering questions intended for the other track.* To make sure, please look for the questions for the other track as soon as you begin and cross them out!

Mark the box of the track you are following:

_ Standard

____ Advanced

1. [Standard Track Only] Grab Bag (13 points)

Mark the following statements as True or False. The exam appendices may be useful for the Hoare logic and STLC questions.

- (a) In Coq, the type False is inhabited by the single value nil.
 □ True □ False
- (b) In Coq, the term (fun $P \Rightarrow \sim P$) has type Prop. \Box True \Box False
- (c) In Coq, the term (fun (P: nat \rightarrow Prop) $\Rightarrow \forall (m:nat), P m$) has type (nat \rightarrow Prop) \rightarrow Prop. \Box True \Box False
- (d) In Coq, if we have a hypothesis H : value t, then the tactic induction H. will generate four new goals, one for each constructor. (The definition of value is in Appendix B.)

```
\Box True \Box False
```

(e) For the following Imp program,

```
{{ X = 10 \lambda Y = 2 \lambda Z = 0 }}
while \simeq(X = 0)
    X := X - Y
    Z := Z + 1
end
{{ Z = 5 }}
```

 $10 = X + Y \times Z \wedge Y = 2$ is a valid loop invariant which can also be used to prove the given Hoare triple.

- \Box True \Box False
- (f) For the same Imp program given in the previous problem, x = z * 2 is a valid loop invariant, but cannot prove the given Hoare triple.

 \Box True \Box False

- (g) According to cequiv, an Imp command that doesn't terminate on any input is equivalent to every program c.
 - \Box True \Box False
- (h) For Imp programs, if c1 is equivalent to c and c2 is also equivalent to c, then for all b, (if b then c1 else c2) is equivalent to c.
 - \Box True \Box False
- (i) In STLC, the term (\x:Bool, if true then false else true) is a value.
 □ True □ False
- (j) The usual purpose of type checking in a programming language is to prevent nontermination caused by divergence.

```
\Box True \Box False
```

- (k) The term (\x:Bool, (\y:Bool, y) True) False will single step to ([x:=True] (\y:Bool, y) True).
 □ True □ False
- (l) If we extend the STLC with fix, it becomes possible to implement programs that diverge (i.e., go into an infinite loop).
 - \Box True \Box False
- (m) In the STLC extended with reference types, the *store typing* ST used in the typing judgment Gamma ; $ST \vdash t \in T$ maps the heap (a.k.a. memory) locations to their static types.

 \Box True \Box False

2. [Standard Only] Extremely Valid Hoare Triples (12 points)

Recall that the definition of the semantics of Hoare triples is given by the following definition.

```
Definition hoare_triple

(P : Assertion) (c : com) (Q : Assertion) : Prop :=

\forall st st',

st =[c ]\Rightarrow st' \rightarrow

P st \rightarrow

Q st'.
```

Appendix A contains a summary of the Imp semantics.

- (a) Give a P such that for all c and all Q, $\{\{P\}\}\ c\ \{\{Q\}\}\ is\ a\ valid$ Hoare triple.
 - P = _____
- (b) Give a c such that for all P and all Q, $\{\{P\}\}\ c\ \{\{Q\}\}\ is\ a\ valid$ Hoare triple.
 - c = _____
- (c) Give a Q such that for all P and all c, $\{\{P\}\}\ c\ \{\{Q\}\}\ is\ a\ valid$ Hoare triple.
 - Q = _____

3. Reverse Hoare Triples (12 points)

Consider this variant of a Hoare triple:

Such a triple is sometimes used for something called *incorrectness logic*, which can help find bugs. The idea is that the post-condition Q specifies an *undesirable state* and the triple says that such a state is reachable (assuming termination) from an initial condition satisfying P.

We use $\langle P \rangle c \langle Q \rangle$ as notation for reverse_triple P c Q, and as usual, we say this triple is *valid* if the proposition holds and *invalid* otherwise. For example, we have the following instances:

```
<<True>> Z := 2 <<Z = 2>> (* this triple is valid - any initial state is OK *)
<<True>> Z := 2 <<Z = 3>> (* this triple is invalid - no initial state works *)
```

The triples below are all invalid. Find counterexamples st' that demonstrates this.

```
(a)
    << False >>
     skip
     << Z = 2 >>
     Counterexample: st' =
(b)
    << True >>
    Z := 2
     << True >>
     Counterexample: st' = _____
(c)
     << Z = 10 >>
     if (X = 1)
        then Z := 42
        else skip
     end
     << Z = 42 >>
     Counterexample: st' =
```

4. Simply-typed Lambda Calculus with Pairs (22 points total)

Appendix B contains the syntax, small-step operational semantics, and typing relation for a variant of the simply-typed lambda calculus with Bool and pair types. Unlike the variant studied in class that used fst and snd "projection" operations, this version uses a pattern-matching operation called "split" to decompose a pair into its components. For instance, if p is a term that evaluates to (v1, v2) then the term let (x,y) = p in x will evaluate (in several steps) to v1. So the complete program below steps as shown:

(\p : Bool * Bool, let (x, y) = p in x) (true, false) \longrightarrow true.

The syntax and rules presented in the appendix are completely identical to those from the course notes except for those marked \bigstar , which have to do with the new split operation. Note that the new syntax let (x,y) = t1 in t2 binds the variables x and y for use in t2.

a. (4 points) As usual, the operational semantics depends on a notion of *substitution* [x:=s]t, which is defined inductively on the structure of t. All of the cases are given in the Appendix except for those dealing with split. Which of the following clauses should we add to the definition to properly define substitution? (Choose one or more.)

```
[x:=s](let (y,z) = t1 in t2)
                                   = let (y,z) = [x:=s]t1 in [x:=s]t2
[x:=s](let (y,z) = t1 in t2)
                                   = let (y,z) = [x:=s]t1 in t2
                                                                         when x=y or x=z
[x:=s](let (y,z) = t1 in t2)
                                   = let (y,z) = t1 in [x:=s]t2
                                                                         when x=y or x=z
[x:=s](let (y,z) = t1 in t2) = let (y,z) = [x:=s]t1 in [x:=s]t2 when x<>y and x<>z
when x<>y and x<>z
     [x:=s](let (y,z) = t1 in t2)
                                   = let (y,z) = t1 in t2
[x:=s](let (x,x) = t1 in t2)
                                   = let (s,s) = [x:=s]t1 in [x:=s]t2
```

- **b.** Using the rules in the appendix, there is exactly one possible typing derivation for the following claim: empty $\vdash \p$: Bool * Bool, let (x,y) = p in $x \in (Bool * Bool) \rightarrow Bool$
 - (i) (3 points) What form will the typing context Gamma have at the point in the derivation where the rule T_Var is used to check the variable p? (Choose one.)
- (ii) (3 points) What form will the typing context Gamma have at the point in the derivation where the rule T_Var is used to check the variable x? (Choose one.)

c. (3 points) Recall that a term is *closed* if it contains no free variables, which means, for well-typed terms, that it typechecks in an empty context. Now consider the following lemma, which would be a useful result about the values in this language:

```
Lemma value_closed: \forall t, value t \rightarrow \exists T, empty \vdash t \in T.
```

Unfortunately, this lemma is not provable. In the space below, provide a counterexample t that refutes the claim.

t =_____.

d. (3 points) Suppose we add the following rule to the step semantics of the language:

```
----- (ST_Pair3)
(s,t) --> (t,s)
```

Which of the following properties will fail for this version of the language?

- □ progress
- □ preservation
- \Box determinacy of evaluation
- \Box (they all remain valid)
- e. (3 points) Suppose instead that we add the following typechecking rule:

Gamma x = T1*T2 ----- (T_Var2) Gamma |- x **in** T1

Which of the following properties will *fail* for this version of the language?

- \Box progress
- \Box preservation
- \Box determinacy of evaluation
- \Box (they all remain valid)
- f. (3 points) Suppose instead we add the following rule to the step semantics of the language:

value s value t
------ (ST_Pair3)
(s,t) --> true

Which of the following properties will fail for this version of the language?

- □ progress
- □ preservation
- \Box determinacy of evaluation
- \Box (they all remain valid)

5. STLC + Boxes (36 points total)

In this problem, we consider a variant of the simply-typed lambda calculus with *boxed* values and a new type "box", written \Box . The type \Box is used to describe a "boxed" value, which is a value tagged with a run-time representation of its type. For instance, we write [true : Bool] for a boxed value true tagged with its type Bool. Similarly, we write [\x:Bool,x : Bool \rightarrow Bool] for a boxed function value $\langle x:Bool, x$ tagged with its type Bool \rightarrow Bool. Importantly, all such boxes, regardless of their contents, have the *same* static type, \Box . So, when we "box" a value, we forget it static type.

To open a box and access its contents, we need to perform a *dynamic* type check that determines whether the contents of the box have a given type, T. We introduce new syntax unbox - for - else, and write unbox t for (\x:T, t1) else t2 for this "dynamic type test" operation. Here, t must be a term that evaluates to a boxed value, [v : U] and the term after for must be (or evaluate to) a function value. Recall that the function argument is annotated with a type T. To evaluate unbox, we check whether T = U, and, if so, the program calls the function on v, otherwise, when the types are different, i.e. T<>U, the else branch is taken.

For example, according to the intended operational semantics we have the following three reduction sequences:

- (1) unbox [true:Bool]for (\x:Bool, x) else false \longrightarrow (\x:Bool, x) true \longrightarrow true (1) applies the function (\x:Bool,x) to true because the type in the box, Bool, equals the type of x
- (2) unbox [true:Bool]for (\f:Bool \rightarrow Bool, f true) else false \longrightarrow false (2) takes the else branch because Bool \Rightarrow (Bool \rightarrow Bool)
- (3) unbox [\x:Bool,x:Bool \rightarrow Bool]for (\f:Bool \rightarrow Bool, f true) else false \longrightarrow (\f:Bool \rightarrow Bool, f true) (\x:Bool, x) \longrightarrow (\x:Bool, x) true \longrightarrow true (3) applies the function because the types are equal

Boxed values are thus a simple model of languages like Python that support "dynamic types" and run-time type dispatch. In this problem we develop a type system and prove type safety for this feature. Appendix C shows the changes to the grammars for types and new terms for this language; the omitted terms are the usual ones for STLC with Bool as in Appendix B. (Note: for simplicity we *do not* include pairs in this problem.) The type system presented in Appendices B & C satisfies all of the key lemmas for STLC.

a. (3 points) Which of the new small-step semantics rules are considered to be *congruence rules*? (Mark all that apply.)

□ ST_Box □ ST_Unbox1 □ ST_Unbox2 □ ST_UnboxEQ □ ST_UnboxNEQ

b. (3 points) Which of the following is the correct statement of the *canonical forms lemma* for the \Box type?

c. (9 points) Recall that the typing rules for STLC+ \Box in Appendices B & C are *syntax directed*, which means that which rule applies at some step of the derivation is uniquely determined by the syntax of the term. We say that such a rule *fails* if the syntax of the term matches the rule, but one or more of the hypotheses of the rule is not satisfied.

For each of the following terms in STLC+ \Box , indicate whether the given typing judgment is derivable using the rules from Appendices B & C. If it is not derivable, write the name of a rule that fails for the derivation (there might be more than one) in the space provided. We have done the first two for you.

```
x \mapsto Bool \vdash x \in Bool
         \boxtimes is derivable \square is not derivable because ______ fails
empty \vdash x \in Bool
                        \boxtimes is not derivable because _____ T_Var fails
         \Box is derivable
empty \vdash [true : Bool] \in \Box
         \Box is derivable
                           \Box is not derivable because
                                                                                            fails
empty \vdash \ x:\Box, unbox x for (\b:Bool, x) else false \in \Box \rightarrow Bool
         \Box is derivable
                         \Box is not derivable because _____
                                                                                             fails
empty \vdash \ x:\square, unbox x for (\b:Bool, b) else (\c:Bool,false) \in \square \rightarrow Bool
         \Box is derivable \Box is not derivable because _____
                                                                                             fails
```

d. (3 points) Suppose we change the typing rule T_Box to the one shown below, rather than the one in the appendix—note that \cup appears as the annotation in the box.

Which of the following properties will *fail* for this version of the language?

- □ progress
- □ preservation
- \Box determinacy of evaluation
- \Box (they all remain valid)

e. (3 points) Suppose we instead change the typing rule T_Box to the one shown below, rather than the one in the appendix—note that t is given type \Box in the premise.

Which of the following properties will *fail* for this version of the language?

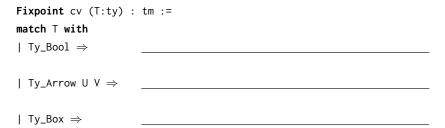

- □ progress
- \Box preservation
- \Box determinacy of evaluation
- \Box (they all remain valid)

f. (3 points) Suppose we instead change the typing rule T_Unbox to the one shown below, rather than the one in the appendix—note that the type of t2 is just U in the premise.

Which of the following properties will *fail* for this version of the language?

- □ progress
- \Box preservation
- \Box determinacy of evaluation
- \Box (they all remain valid)

g. (6 points) It turns out that, because STLC+ \Box is so simple, there is a *closed* value for any type τ . Fill in the blanks below to complete the function to produce such a value.

end.

Your code above should be such that the following lemma holds:

Lemma 1 (Values of any type). \forall T, value (cv T) \land empty \vdash (cv T) \in T

The addition of this "box" construct does not seem that powerful at first glance, because it simply lets us write programs that test for type information at runtime. However, it is now possible to write a program that, when run, goes into an infinite loop—something that is impossible in just STLC! (And, with a bit more work, it is possible to implement the fix operator that implements general recursion.)

h. (3 points) To see how, first note that there is a type \top such that the following judgment is derivable according to the rules of STLC+ \Box . (There is only one possible type for this program.)

empty $\vdash \ x:\square$, unbox x for (\f:T, f x) else x \in T

What type can be filled in for T?

 $\Box T = \Box$ $\Box T = \Box \rightarrow \Box$ $\Box T = (\Box \rightarrow \Box) \rightarrow \Box$ $\Box T = \Box \rightarrow \Box \rightarrow \Box$

i. (3 points) Next, let us abbreviate the program above as m:

m = $x:\Box$, unbox x for (f:T, f x) else x

Then, for some type U, we also have this well-typed program: $empty \vdash m [m:T] \in U$. Looking at the operational semantics, we have the following sequence of steps, which demonstrates the infinite loop:

 $\texttt{m} \texttt{[m:T]} \longrightarrow \texttt{?} \longrightarrow \ldots \longrightarrow \texttt{m} \texttt{[m:T]}$

What term should be filled in for ? above as the result of the first step of evaluation?

 \Box unbox m for (\f:T, f m) else m

 \Box unbox [m:T] for (\f:T, f [m:T]) else [m:T]

How many more steps (after this first one) does it take to reach m [m:T] for the first time?

(Note: Advanced Track students may want to continue to problem 7 before doing problem 6.)

6. Subtyping (15 points total)

Appendix E contains the additions needed to add subtyping to the simply-typed lambda calculus defined in Appendix B. In particular we extend the types T to include Top, add the *subsumption* rule T_Sub to the type system, and define type subtyping relation s <: T as shown in the appendix. The definition of values, substitution, and the small-step semantics remain unchanged.

a. (5 points) For each of claims below, mark the box if it is a *valid* subtyping relation according to the rules in Appendix E.

```
□ Top <: Bool

□ (Bool, Bool) <: (Top, Bool)

□ (Bool → Top) → Bool <: (Top → Bool) → Bool.

□ (Bool → Top) → (Bool → Bool) <: (Top → Bool) → Top.

□ (Bool → Top) → (Bool → Bool) <: Top → Top
```

b. (5 points) Give a *short* example term of that is well-typed at type Bool in the empty context and such that its typing derivation *must* use the rule T_Sub . Then fill in the blanks below to indicate which types are needed for the use of T_Sub

empty ⊢	$\in \texttt{Bool}$
The derivation relies on an instance of T_Sub in which:	
T1 =	
T2 =	

c. (2 points) How many types \cup exist such that Bool <: \cup (according to the rules of in the appendix?) (choose one)

 \Box 0 \Box 1 \Box 2 \Box infinitely many

d. (3 points) We saw in class that there are various *inversion* lemmas related to subtyping. For instance, we proved that $\forall U, U \leq Bool \rightarrow U = Bool$. Here we consider the inversion of *supertypes*. What is the appropriate property that can be filled in for ??? such that the following lemma is provable? (choose one)

Lemma sub_inversion_pair2 : \forall S1 S2, S1 * S2 <: U \rightarrow ???

□ U = Top

□ ∃ T1 T2, U <: T1 * T2

 \Box ~ U = Top \lor \exists T1 T2, U = T1 * T2 \land T1 <: S1 \land T2 <: S2

 \Box U = Top \lor \exists T1 T2, U = T1 * T2 \land S1 <: T1 \land S2 <: T2

□ False

7. [Advanced Only] Formal Proof (25 points total)

A program translation is called *type directed* when it is defined by using the structure of the typing derivation for a (well-typed) term. In this problem, we prove that a simple translation preserves typing. Appendix D defines a type-directed translation on the STCL+ \Box language used in Problem 5. This translation "boxes" the type Bool in a source program by replacing Bool with \Box and putting boolean constants into boxes. The hard part is unboxing them for use in conditionals.

The translation is given in two parts. First, we define a type translation T^{\dagger}_{\dagger} that converts each occurrence of Bool in T into \Box . Its definition is shown at the top of Appendix D. Then we define a type-directed translation judgment Gamma $\vdash t \rightsquigarrow t' \in T$. This judgment indicates that the source term t translates to the target term t'. The rules that define the translation (also given in Appendix D) are inductive, and they mirror the typing rules—in particular, the context Gamma and the type T correspond to the *source* program (they don't have translated types). As such, we can think of this translation as "decorating" a typing derivation of the program t, and it is easy to prove by straight-forward induction the following lemma:

Lemma 2 (Well-typed Source). If Gamma $\vdash t \rightsquigarrow t' \in T$ then Gamma $\vdash t \in T$.

In this problem you will prove the more interesting result, namely:

Lemma 3 (Well-typed Target). *If* Gamma $\vdash t \rightsquigarrow t' \in T$ *then* Gamma $\dagger \vdash t' \in T^{\dagger}_{\uparrow}$.

Here, Gamma⁺ is the "translated" target context, i.e., the one such that Gamma x = Some T \leftrightarrow Gamma⁺ x = Some (T⁺).

Looking carefully at the translation, you will see that it mostly the identity—most rules just apply the translation recursively to the subterms. However, note that the type annotations in lambda abstraction and boxes are translated. The interesting rules are TR_True and TR_False, which replace Boolean constants by their boxed versions, and, most interestingly, the TR_If rule.

TR_If unboxes the guard expression t1' as a Bool to perform the conditional. There are two wrinkles. First, because the unbox operation needs a function, this translation introduces new lambda-bound variables, which must not otherwise be used in Gamma—we write "x is fresh for Gamma" to indicate that. Second, the unbox operation needs an "else" case, which should be the same type as the (translated) branches, but those are of type T1†. Our translation will ensure (though we will not prove it) that the unboxing never fails, so it doesn't matter what term we put as the "else" case; but nevertheless, we need to provide some term, which we write as error T1†.

a. (3 points) Let us address the second problem first. In the Problem 5, we implemented a function cv that can produce well-typed values of any type. We can therefore take error T = cv T and prove:

Lemma 4 (Error well typed). Gamma ⊢error T1†: T1†

Proof. The proof follows immediately from Lemma 1 plus a use of: (choose 1)

- □ Substitution preserves typing
- □ Weakening
- \Box Preservation
- Canonical forms

[Advanced Only]

b. To handle the problem that the translation introduces new variables, we need to more carefully account for how the source and target contexts are related. We therefore define the following inductive relation $\subseteq \dagger$, which explains how a context Gamma relates to a translated context Gamma'.

We have the following lemma:

Lemma 5 (Translated Contexts).

 $\forall \; \text{Gamma Gamma' x T, \; \text{Gamma} \subseteq \dagger \text{Gamma'} \rightarrow \text{Gamma x = Some T} \rightarrow \text{Gamma' x = Some T}^{\dagger}_{\uparrow}_{\downarrow}.$

We can finally state a strong enough lemma to prove that the translation produces well-typed terms. Fill in the three indicated cases (we omit the other cases) to complete the proof. You may use Lemmas 4 and 5 where needed. In the inductive cases, be explicit about the form of any induction hypotheses and how you use them, and indicate the inference rules using the names provided.

 $\begin{array}{l} \text{Lemma 6} \text{ (Translation well-typed).} \\ \forall \text{ Gamma t t' T, Gamma } \vdash t \sim t' \in T \rightarrow \forall \text{Gamma', Gamma} \subseteq \dagger \text{Gamma'} \rightarrow \text{Gamma'} \vdash t' \in T \dagger . \end{array}$

Proof. The proof proceeds by induction on the derivation that $Gamma \vdash t \rightsquigarrow t' \in T$. We consider that cases based on the last rule applied in the derivation. Most of them follow by straightforward induction; we consider the most interesting cases below:

Case TR_Var (4 points) Then t = x and t' = x and we have Gamma x = Some T and, by assumption Gamma $\subseteq \frac{1}{\text{Gamma}}$. We need to show...

Fill in here:

[Advanced Only]

Case TR_Abs (8 points) Then $T = U \rightarrow V$ for some U and V and we have $t = \langle x:U, t1 \text{ for some x and } t1$. We also have $t' = \langle x:U^{\dagger}, t1', where we know (x \mapsto U; Gamma) \vdash t1 \rightarrow t1' \in V$. Furthermore, Gamma $\subseteq \dagger$ Gamma'. We need to show...

[Advanced Only]

Case TR_If (10 points) Then t = if t1 then t2 else t3 for some t1, t2, and t3, where we also know that Gamma \vdash t1 \rightarrow t1' \in Bool and Gamma \vdash t2 \rightarrow t2' \in U and Gamma \vdash t3 \rightarrow t3' \in U for some U. Furthermore, Gamma \subseteq \ddagger Gamma'.The translated term t' is unbox t1' for (\x:Bool, if x then t2' else t3') else (error U \ddagger), where x is fresh for Gamma. We must show that...

Appendix B: Simply-typed Lambda Calculus

This appendix contains the syntax, small-step operational semantics, and typing relation for a variant of the simply-typed lambda calculus with Bool and pair types. Unlike the variant studied in class (which used fst and snd "projection" operations), this version uses a pattern-matching operation called "split" to decompose a product into its components. The syntax and rules presented here are completely identical to those from the course notes except for those marked \bigstar , which have to do with the new split operation.

Syntax and Types

t ::= Terms | x variable | \x:T,t abstraction | t t application | true constant true | false constant false | if t then t else t conditional | (t, t) pair | let (x,y) = t in t split ★ T ::= Types $| T \rightarrow T$ arrow type | Bool Boolean type | T * T product type **Inductive** value : tm \rightarrow Prop := | v_abs : \forall x T2 t1, value <{\x:T2, t1}> | v_true : value <{ true }> | v_false : value <{ false }> | v_pair : \forall v1 v2, value v1 \rightarrow value v2 \rightarrow value <{(v1, v2)}>.

Substitution

Note: this definition is *incomplete*.

```
= s
[x:=s]x
[x:=s]y
                   = y
                                            if x <> y
                 = \x:T, t
= \y:T, [x:=s]t
[x:=s](x:T, t)
[x:=s](\y:T, t)
                                            if x <> y
[x:=s](t1 t2)
                    = ([x:=s]t1) ([x:=s]t2)
[x:=s]true
                    = true
[x:=s]false
                    = false
[x:=s](if t1 then t2 else t3) =
      if [x:=s]t1 then [x:=s]t2 else [x:=s]t3
[x:=s](t1, t2) = ([x:=s]t1, [x:=s]t2)
[x:=s](let (y,z) = t1 in t2) =
                                            ★
   // omitted
```
